## Abstract

We study contributions of quark-squark-gluino interactions in Minimal Supersymmetric Standard Model (MSSM) to $B \to PP$ ($PP = K\pi, \pi\pi, KK$) decays using QCD improved factorization method for the evaluation of the hadronic matrix elements and taking into account renormalization group running of the Wilson coefficients from SUSY scale ($\approx m_{\tilde{q}}$) to the low energy scale ($= m_b$) applicable to $B$ decays. Using the most recent experimental data we obtain constraints on flavor changing Supersymmetric (SUSY) parameters $(\delta_{ij})_{LL,RR}$. For $\Delta S = -1$ processes, $b \to s\gamma$ is usually considered to give the strongest limits. We, however, find that in some part of the parameter space $B \to K\pi$ processes give stronger bounds. Implications for $B^0_s - \bar{B}^0_s$ mixing is discussed. We also study constraints obtained from $\Delta S = 0$ processes $B \to \pi\pi, KK, \rho\gamma$ and $B_d - \bar{B}_d$ mixing. In this case, in a large part of the parameter space $B_d - \bar{B}_d$ provides the best bound, but $B \to K^- K^0, \rho\gamma$ can still give interesting constraints in a complementary region of the parameter space.

## I. INTRODUCTION

Recent results from $B$-factories at CLEO, BaBar, Belle have attracted a lot of attentions. Data from these experiments provide new opportunities to further study the Standard Model (SM) and also to study physics beyond the SM. Rare charmless hadronic $B$ decays, such as $B \to PP (PP = K\pi, \pi\pi, KK)$, are particularly interesting. These processes being rare are sensitive to new physics beyond the SM. Minimal Supersymmetric Standard Model (MSSM), which is an extension of the SM emerges as one of the most promising candidates for new physics beyond the SM. MSSM resolve many of the potential problem of the SM, for example the hierarchy problem, unification of $SU(3) \times SU(2) \times U(1)$ gauge couplings, and so on [1].

$B \to PP$ decays have been studied extensively within the framework of naive factorization scheme. In the last few years, QCD improved factorization method have been developed. This method incorporates elements of the naive factorization approach (as its leading term) and perturbative QCD corrections (as subleading contributions) allowing one to compute systematic radiative corrections to the naive factorization for the hadronic $B$ decays [2,3]. This method provides a better understanding of the strong interaction dynamics for $B$ decay into two light mesons. Therefore results obtained using QCD improved method are expected to be more reliable compared with those obtained by using naive factorization. Lot of studies have been done in this direction so far [4,5].

In this paper we study implications of the recently measured $B \to PP$ branching ratios on SUSY flavor changing parameters, specially arising from the quark-squark-gluino ($q - \tilde{q} - \tilde{g}$) interactions in the model [6]. Effects of SUSY interactions on various processes involving $B$ mesons have been studied previously [6–11]. Here we will concentrate on the $q - \tilde{q} - \tilde{g}$ interactions and re-analyze $B \to PP$ decays with several improvements. Firstly we use the QCD improved factorization method to compute the two body hadronic $B$ decays. Secondly, we improve the quark level effective Hamiltonian by including QCD running of different Wilson coefficients (WC) from the SUSY scale ($= m_{\tilde{q}}$) to the low energy scale ($= m_b$) which is applicable to $B$ decays. Previous authors while doing similar analysis have neglected this

RG evolution of WC's. We find that this RG evolution of WC's have non-negligible effects on the branching ratio calculations.

Using the most recent experimental data from different $B$-factories on the $B \to PP$ decays we constrain the flavor changing SUSY parameters arising from the $\tilde{q}_{iLR} - \tilde{q}_{jLR}$ mixing due to the presence of $q - \tilde{q} - \tilde{g}$ interaction vertices in different one loop contributions to $B \to PP$ decays. Similar kind of squark mixing can also occur for other flavor changing $B$ decays. For $\Delta S = -1$ processes, $b \to s\gamma$ is usually considered to give the strongest limit on such mixing. We, however, find that in some part of the parameter space $B \to K\pi$ processes provide better bound. We also discuss the implications of $B_s^0 - \bar{B}_s^0$ mixing in this context. Furthermore, we also study constraints on FCNC parameters obtained from $\Delta S = 0$ processes $B \to \pi\pi, KK, \rho\gamma$, and $B_b - \bar{B}_d$ mixing. We find that $B_d^0 - \bar{B}_d^0$ mixing provides the best limit in a large part of the parameter space, but in certain region of the parameter space $B \to \pi\pi, KK, \rho\gamma$ can still give better constraints.

## II. SQUARK-GLUINO CONTRIBUTIONS TO $B \to PP$ DECAYS

In the SUSY, squark and gluino induce large one loop contribution to $B \to PP$ decay from penguin and box diagrams because they are related to strong couplings. We compute the effect of flavor changing contributions to $B \to PP$ arising from $q - \tilde{q} - \tilde{g}$ interaction vertices using the mass insertion approximation method [6,12]. In this method, the basis of the quark and squark states are chosen in such a way that their couplings with gluinos are flavor diagonal. The flavor changing current arises from the non-diagonality of the squark propagators. We denote the off-diagonal terms in the squark mass matrices (i.e. the mass terms relating squark of the same electric charge, but different flavor), by $\Delta$, then we expand the squark propagators as series in terms of $(\delta_{ij})_{AB} = (\Delta_{ij})_{AB}/\tilde{m}^2$ where $\tilde{m}$ is an average squark mass, $A, B = L, R$ and $i, j$ are the generation indices. The notation $(\delta_{13})_{AB}$ and $(\delta_{23})_{AB}$ denote $\tilde{d} - \tilde{b}$ and $\tilde{s} - \tilde{b}$ mixing respectively. These two parameters signify the size of flavor changing interactions in SUSY through the $q - \tilde{q} - \tilde{g}$ interactions.

At one loop level, for $\tilde{q}_L - \tilde{q}_L$ mixing ($LL$ type ), the new effective Hamiltonian relevant to $B \to K\pi, \pi\pi$ decays arise from SUSY penguin and box diagrams with gluino-squark in the loops is given by

$$H_{eff}^{susy} = -\frac{G_F}{\sqrt{2}} V_{tb} V_{tq}^* \sum_{i=3}^{6} C_i^{LL} O_i. \tag{1}$$

Here we have normalized the WC's according to the SM ones. The operator $O_i$ is the same as SM definition with

$$\begin{aligned} O_3 &= \bar{q}_i \gamma^\mu L b_i \sum_{q'} \bar{q}'_j \gamma_\mu L q'_j, \quad O_4 = \bar{q}_i \gamma^\mu L b_j \sum_{q'} \bar{q}'_j \gamma_\mu L q'_i, \\ O_5 &= \bar{q}_i \gamma^\mu L b_i \sum_{q'} \bar{q}'_j \gamma_\mu R q'_j, \quad O_6 = \bar{q}_i \gamma^\mu L b_j \sum_{q'} \bar{q}'_j \gamma_\mu R q'_i, \end{aligned} \tag{2}$$

where $L(R) = (1 \pm \gamma_5)$, $q = d, s$, $q' = u, d, s$. The WC's are given by [6]:

$$\begin{aligned} C_3^{LL}(M_{susy}) &= \frac{-\alpha_s^2}{2\sqrt{2} G_F V_{tb} V_{tq}^* m_{\tilde{q}}^2} (\delta_{j3})_{LL} \left( -\frac{1}{9} \mathrm{B}_1(x) - \frac{5}{9} \mathrm{B}_2(x) - \frac{1}{18} \mathrm{P}_1(x) - \frac{1}{2} \mathrm{P}_2(x) \right) \\ C_4^{LL}(M_{susy}) &= \frac{-\alpha_s^2}{2\sqrt{2} G_F V_{tb} V_{tq}^* m_{\tilde{q}}^2} (\delta_{j3})_{LL} \left( -\frac{7}{3} \mathrm{B}_1(x) + \frac{1}{3} \mathrm{B}_2(x) + \frac{1}{6} \mathrm{P}_1(x) + \frac{3}{2} \mathrm{P}_2(x) \right) \\ C_5^{LL}(M_{susy}) &= \frac{-\alpha_s^2}{2\sqrt{2} G_F V_{tb} V_{tq}^* m_{\tilde{q}}^2} (\delta_{j3})_{LL} \left( \frac{10}{9} \mathrm{B}_1(x) + \frac{1}{18} \mathrm{B}_2(x) - \frac{1}{18} \mathrm{P}_1(x) - \frac{1}{2} \mathrm{P}_2(x) \right) \\ C_6^{LL}(M_{susy}) &= \frac{-\alpha_s^2}{2\sqrt{2} G_F V_{tb} V_{tq}^* m_{\tilde{q}}^2} (\delta_{j3})_{LL} \left( -\frac{2}{3} \mathrm{B}_1(x) + \frac{7}{6} \mathrm{B}_2(x) + \frac{1}{6} \mathrm{P}_1(x) + \frac{3}{2} \mathrm{P}_2(x) \right) \end{aligned} \tag{3}$$

where $j = 1, 2$ when $q = d, s$, respectively and $x = m_{\tilde{g}}^2 / m_{\tilde{q}}^2$ . The definition of the functions $B_i(x), P_i(x)$ can be found in Ref [6].

The above WC's are obtained at the SUSY scale $M_{susy}$. We take this scale as $m_{\tilde{q}}$. We then evolve these WC's from this high scale down to the scale $m_b$ using the RG equation. At the lower scale, after the RG evolution, the WC's take following form:

$$\begin{aligned} C_3^{LL}(m_b) &= b_3^3 C_3^{LL}(M_{susy}) + b_3^4 C_4^{LL}(M_{susy}) + b_3^5 C_5^{LL}(M_{susy}) + b_3^6 C_6^{LL}(M_{susy}) \\ C_4^{LL}(m_b) &= b_4^3 C_3^{LL}(M_{susy}) + b_4^4 C_4^{LL}(M_{susy}) + b_4^5 C_5^{LL}(M_{susy}) + b_4^6 C_6^{LL}(M_{susy}) \\ C_5^{LL}(m_b) &= b_5^3 C_3^{LL}(M_{susy}) + b_5^4 C_4^{LL}(M_{susy}) + b_5^5 C_5^{LL}(M_{susy}) + b_5^6 C_6^{LL}(M_{susy}) \\ C_6^{LL}(m_b) &= b_6^3 C_3^{LL}(M_{susy}) + b_6^4 C_4^{LL}(M_{susy}) + b_6^5 C_5^{LL}(M_{susy}) + b_6^6 C_6^{LL}(M_{susy}) \end{aligned} \tag{4}$$

| $M_{susy}$ (GeV) | $b_3^3$ | $b_3^4$ | $b_3^5$ | $b_3^6$ | $b_4^3$ | $b_4^4$ | $b_4^5$ | $b_4^6$ |

TABLE I. Values of different WC's after RG evolution for three values of $M_{susy} = 100, 500$ and 1000 GeV.

$b_i^j$ are the constant after running, depend on the choice of the initial scale, as shown in Table. I.

We find that the WC's with and without the RG evolution can be different by a factor of two in some cases. This implies that to have a reliable result and consistent computation one has to take into account the RG evolution of WC's.

Apart from $LL$ type of operators, one can also have operators with different chiral structures, such as $RR$, $LR$ and $RL$ type. The operators and WC's for $RR$ mixing can be obtained by the exchange $L \leftrightarrow R$ in Eqs. 2 and 3. $LR$ and $RL$ mixing cases can also be easily studied. However, in these two cases there are more stringent constraints from gluonic dipole moment operators for $B \to PP$ decays. The details have been studied in [13]. We will not discuss these two cases further.

## III. DECAY AMPLITUDES FROM QCD IMPROVED FACTORIZATION

To obtain the branching ratios of $B \to PP$ decays, one needs to study the matrix elements, $< PP|H_{eff}|B >$. The usual approach is the naive factorization method, where the hadronic matrix element can be approximated as a product of two single current matrix elements, then it is parametrized into meson decay constant and meson-meson transition form factor.

Previous analysis of SUSY contribution to $B \to PP$ decays have been performed using the above mentioned naive factorization method. However, in the present analysis we will use the QCD improved factorization approach [2] to compute the SUSY effects to the $B \to PP$ decays. This formalism incorporates the basic elements of naive factorization approach as its leading term and perturbative QCD corrections as subleading contributions allowing one to calculate radiative corrections to the naive factorization for the hadronic two body decays of $B$ meson.

In our case the total effective Hamiltonian for $B \to PP$ decays have two sources, the usual SM part $H_{eff}^{SM}$ and the SUSY part $H_{eff}^{susy}$. We use the SM results obtained in Ref. [2]. The results for the two types of SUSY contribution from $LL$ and $RR$ mixing can be easily obtained once one understands the SM contributions since the operators from SUSY interactions discussed here are all strong penguin type. In the $LL$ mixing case, the total WC's are the sum of SM WC ($C_{3..6}^{SM}$) and SUSY contributions.

$$\begin{aligned} C_3^{total} &= C_3^{SM} + C_3^{LL}, \quad C_4^{total} = C_4^{SM} + C_4^{LL}, \\ C_5^{total} &= C_5^{SM} + C_5^{LL}, \quad C_6^{total} = C_6^{SM} + C_6^{LL}. \end{aligned} \tag{5}$$

For $RR$ mixing, due to the different chirality of the new operators the total WC's in the final results are replaced by $C_{3,4,5,6}^{total} = C_{3,4,5,6}^{SM} - C_{3,4,5,6}^{RR}$. The two type of mixing, $LL$ and $RR$ have similar contributions. Knowing how one of them affects $B \to K\pi, \pi\pi$ decays, the other can be easily estimated.

We write down the decay amplitude of $\bar{B}^0 \to \pi^+\pi^-, K^-\pi^+$ for an illustration,

$$\begin{aligned} A(\bar{B}^0 \to \pi^+\pi^-) &= \frac{G_F}{\sqrt{2}} i f_\pi (m_B^2 - m_\pi^2) F^{B\to\pi}(0) \Big[ V_{ub}V_{ud}^*(a_1 + a_4^u + a_{10}^u \\ &\quad + R_\pi(a_6^u + a_8^u)) + V_{cb}V_{cd}^*(a_4^c + a_{10}^c + R_\pi(a_6^c + a_8^c)) \Big] \\ &\quad + i\frac{G_F}{\sqrt{2}} f_B f_\pi^2 \Big[ V_{ub}V_{ud}^* b_1 + (V_{ub}V_{ud}^* + V_{cb}V_{cd}^*)\Big(b_3 + 2b_4 - \frac{1}{2}b_3^{ew} + \frac{1}{2}b_4^{ew}\Big)\Big] \end{aligned} \tag{6}$$

$$A(\bar{B}^0 \to K^-\pi^+) = \frac{G_F}{\sqrt{2}} i f_K (m_B^2 - m_K^2) F_0^{B\to\pi}(m_K^2) [V_{ub}V_{us}^*(a_1 + a_4^u + a_{10}^u + R_K(a_6^u + a_8^u))$$

$$
\begin{aligned}
&+V_{cb}V_{cs}^*(a_4^c + a_{10}^c + R_K(a_6^c + a_8^c)] \\
&+\frac{G_F}{\sqrt{2}} i f_B f_\pi f_K (V_{ub}V_{us}^* + V_{cb}V_{cs}^*)(b_3 - \frac{1}{2}b_3^{ew})
\end{aligned}
\tag{7}
$$

Similarly for other $B \to K\pi, \pi\pi, KK$ modes.

Here $R_K = 2m_K^2/m_s m_b$. $a_i$ and $b_i$ coefficients are related to the WC's. Including the lowest $\alpha_s$ order corrections, $a_i^q$'s are given by

$$
\begin{aligned}
a_1 &= C_1 + \frac{C_2}{N}\left[1 + \frac{C_F\alpha_s}{4\pi}V_K\right] + \frac{C_2}{N_c}\frac{C_F\pi\alpha_s}{N_c}H_{K\pi} \\
a_2 &= C_2 + \frac{C_1}{N}\left[1 + \frac{C_F\alpha_s}{4\pi}V_\pi\right] + \frac{C_1}{N_c}\frac{C_F\pi\alpha_s}{N_c}H_{\pi K} \\
a_4^p &= C_4^{total} + \frac{C_3^{total}}{N}\left[1 + \frac{C_F\alpha_s}{4\pi}V_K\right] + \frac{C_F\alpha_s}{4\pi}\frac{P_{K,2}^p}{N_c} + \frac{C_3^{total}}{N_c}\frac{C_F\pi\alpha_s}{N_c}H_{K\pi} \\
a_6^p &= C_6^{total} + \frac{C_5^{total}}{N}\left[1 - 6\cdot\frac{C_F\alpha_s}{4\pi}\right] + \frac{C_F\alpha_s}{4\pi}\frac{P_{K,3}^p}{N_c} \\
a_7 &= C_7 + \frac{C_8}{N}\left[1 + \frac{C_F\alpha_s}{4\pi}(-V_\pi')\right] + \frac{C_8}{N_c}\frac{C_F\pi\alpha_s}{N_c}(-H_{\pi K}') \\
a_8^p &= C_8 + \frac{C_7}{N}\left[1 - 6\cdot\frac{C_F\alpha_s}{4\pi}\right] + \frac{\alpha_{em}}{9\pi}\frac{P_{K,3}^{p,EW}}{N_c} \\
a_9 &= C_9 + \frac{C_{10}}{N}\left[1 + \frac{C_F\alpha_s}{4\pi}V_\pi\right] + \frac{C_{10}}{N_c}\frac{C_F\pi\alpha_s}{N_c}H_{\pi K} \\
a_{10}^p &= C_{10} + \frac{C_9}{N}\left[1 + \frac{C_F\alpha_s}{4\pi}V_K\right] + \frac{\alpha_{em}}{9\pi}\frac{P_{K,2}^{p,EW}}{N_c} + \frac{C_9}{N_c}\frac{C_F\pi\alpha_s}{N_c}H_{K\pi}
\end{aligned}
\tag{8}
$$

where $C_F = (N_c^2 - 1)/(2N_c)$, and $N_c = 3$. The quantities $V_M^{(\prime)}$, $H_{M_2M_1}^{(\prime)}$, $P_{K,2}^p$, $P_{K,3}^p$, $P_{K,2}^{p,EW}$ and $P_{K,3}^{p,EW}$ are hadronic parameters that contain all nonperturbative dynamics. The vertex corrections $V_M$ ($M = \pi, K$) are given by

$$
V_M = 12\ln\frac{m_b}{\mu} - 18 + \int_0^1 dx g(x)\phi_M(x) \tag{9}
$$

$$
V_M' = 12\ln\frac{m_b}{\mu} - 6 + \int_0^1 dx g(1-x)\phi_M(x) \tag{10}
$$

$$
g(x) = 3(\frac{1-2x}{1-x}\ln(x) - i\pi) + \Big[2Li_2(x) - \ln^2(x) + \frac{2\ln(x)}{1-x} - (3 + 2i\pi) - (x \leftrightarrow 1-x)\Big]. \tag{11}
$$

where $\phi_M(x)$ is the leading-twist light cone distribution amplitude of light pseudoscalar meson [14]. This distribution amplitude can be expanded in Gegenbauer polynomials. We truncate this expansion at $n = 2$.

$$\phi_M(x,\mu) = 6x(1-x)\left[1+\alpha_1^M(\mu)C_1^{(3/2)}(2x-1)+\alpha_2^M(\mu)C_2^{(3/2)(2x-1)}\right] \tag{12}$$

where $C_1^{(3/2)}(u) = 3u$ and $C_2^{(3/2)}(u) = \frac{3}{2}(5u^2-1)$. The distribution amplitude parameters $\alpha_{1,2}^M$ for $M = K, \pi$ are: $\alpha_1^K = 0.3$, $\alpha_2^K = 0.1$, $\alpha_1^\pi = 0$ and $\alpha_2^\pi = 0.1$. The detailed expressions can be found in [2].

For the penguin contributions, $P_{K,2}^p$, $P_{K,3}^p$, $P_{K,2}^{p,EW}$ and $P_{K,3}^{p,EW}$ are given by

$$\begin{aligned}
P_{K,2}^p &= C_1\left[\frac{4}{3}\ln\frac{m_b}{\mu}+\frac{2}{3}-G_K(s_p)\right]+C_3^{total}\left[\frac{8}{3}\ln\frac{m_b}{\mu}+\frac{4}{3}-G_K(0)-G_K(1)\right]\\
&\quad +(C_4^{total}+C_6^{total})\left[\frac{4n_f}{3}\ln\frac{m_b}{\mu}-(n_f-2)G_K(0)-G_K(s_c)-G_K(1)\right]\\
&\quad -2C_{11}\int_0^1\frac{dx}{1-x}\phi_K(x)\\
P_{K,2}^{p,EW} &= (C_1+N_cC_2)\left[\frac{4}{3}\ln\frac{m_b}{\mu}+\frac{2}{3}-G_K(s_p)\right]-3C_{12}\int_0^1\frac{dx}{1-x}\phi_K(x)\\
P_{K,3}^p &= C_1\left[\frac{4}{3}\ln\frac{m_b}{\mu}+\frac{2}{3}-\hat{G}_K(s_p)\right]+C_3^{total}\left[\frac{8}{3}\ln\frac{m_b}{\mu}+\frac{4}{3}-\hat{G}_K(0)-\hat{G}_K(1)\right]\\
&\quad +(C_4^{total}+C_6^{total})\left[\frac{4n_f}{3}\ln\frac{m_b}{\mu}-(n_f-2)\hat{G}_K(0)-\hat{G}_K(s_c)-\hat{G}_K(1)\right]-2C_{11}\\
P_{K,3}^{p,EW} &= (C_1+N_cC_2)\left[\frac{4}{3}\ln\frac{m_b}{\mu}+\frac{2}{3}-\hat{G}_K(s_p)\right]-3C_{12}
\end{aligned} \tag{13}$$

with

$$\begin{aligned}
G_K(s) &= \int_0^1 dxG_K(s-i\epsilon,1-x)\phi_K(x)\\
\hat{G}_K(s) &= \int_0^1 dxG_K(s-i\epsilon,1-x)\phi_p^K(x)\\
G_K(s,x) &= -4\int_0^1 duu(1-u)\ln[s-u(1-u)x]
\end{aligned} \tag{14}$$

where $\phi_p(x) = 1$.

The hard spectator contributions to the coefficients $a_i$'s are parametrized in terms of a single (complex) quantity $H'_{M_1M_2}$ which suffers from large theoretical uncertainties related to the regularization of the divergent endpoint integral. Following [2] we use $H_{\pi K} = H_{KK} = 0.99$ at the scale $\mu = m_b$ and

$$H'_{\pi K} = H_{\pi K}, \qquad H_{K\pi} = R_{\pi K}H_{\pi K}. \tag{15}$$

All scale-dependent quantities for hard spectator contributions are evaluated at $\mu_h = \sqrt{\Lambda_h m_b}$ with $\Lambda_h = 0.5$ GeV.

Terms containing the coefficients $b_i$ and $b_i^{ew}$ are from annihilation contributions. The annihilation coefficients are

$$\begin{aligned}
b_1 &= \frac{C_F}{N_c^2} C_2 A_1^i, \quad b_3 = \frac{C_F}{N_c^2}[C_3^{total} A_1^i + C_5^{total}(A_3^i + A_3^f) + N_c C_6^{total} A_3^f] \\
b_2 &= \frac{C_F}{N_c^2} C_2 A_1^i, \quad b_4 = \frac{C_F}{N_c^2}[C_4^{total} A_1^i + C_6^{total} A_2^i] \\
b_3^{ew} &= \frac{C_F}{N_c^2}[C_9 A_1^i + C_7(A_3^i + A_3^f) + N_c C_8 A_3^f] \\
b_4^{ew} &= \frac{C_F}{N_c^2}[C_{10} A_1^i + C_8 A_2^i]. \qquad (16)
\end{aligned}$$

with

$$\begin{aligned}
A_1^i &= A_2^i = \pi\alpha_s \left[18\left(X_A - 4 + \frac{\pi^2}{3}\right) + 2r_\chi^2 X_A^2\right] \\
A_3^f &= 12\pi\alpha_s r_\chi^2 (2X_A^2 - X_A) \qquad (17)
\end{aligned}$$

where $r_\chi = 2\mu_h/m_b$, $X_A = \int_0^1 dy/y$ parameterizes the divergent endpoint integrals. We use $X_A = \ln(m_B/\Lambda_h)$. All scale dependent quantities for annihilation contributions are evaluated at $\mu_h$.

In the QCD improved factorization method the weak annihilation contributions are power suppressed as $\Lambda_{QCD}/m_b$ and hence do not appear in the factorization formula. Apart from this, they also show end-point singularities even at twist-two order in the light-cone expansion of the final state light mesons and therefore can not be calculated systematically in the context of hard scattering approach. One can bypass this problem, by treating these different end-point singularities as a phenomenological parameters. But this induces model dependence and numerical uncertainties in the calculation.

Using the above technique we compute the different two-body branching ratios of $B$ mesons within the framework of SUSY and compare the calculated results with the experimental data to constrain the different flavor changing parameters of SUSY. The experimental branching ratios used in this analysis are listed in Table II. We average the data from CLEO, BaBar, Belle $B$-factories as their results are uncorrelated. To impose the limit on these flavor changing parameters we require that the theoretically computed branching ratios should not deviate from the experimental measurement by $2\sigma$. If the experimental branching ratio has only upper limit, we select the most stringent one from the experimental data. It is clear from Table II that for $B \to \pi^0\pi^0$ and $B \to KK$ modes have only the 90% C.L. upper limit.

TABLE II. The branching ratios for $B \to PP$ in units of $10^{-6}$.

| Branching ratio and CP asymmetries | Cleo [15] | Belle [16] | Babar [17] | Averaged Value |
|---|---|---|---|---|

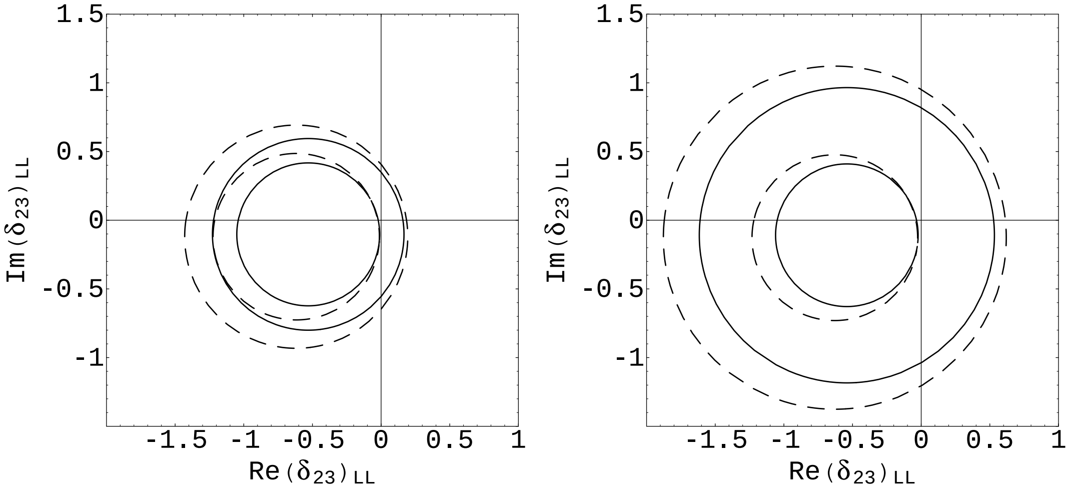
For our numerical calculations, we use $m_b(m_b) = 4.2$ GeV for the b quark mass, $m_c(m_b) = 1.3 \pm 0.2$ GeV, $m_s(2 \text{ GeV}) = 110.0 \pm 0.25$ MeV, $(m_u + m_d)(2\text{GeV}) = 9.1 \pm 2.1$ MeV. For the decay constants and form factors, we use $f_\pi = 0.131$ GeV, $f_K = 0.160$ GeV, $f_B = 0.180$ GeV, $F^{B\to\pi} = 0.28$, $r_{\pi K} \simeq \frac{F^{B\to K} f_\pi}{F^{B\to\pi} f_K} = 0.9$ [2,18]. For the CKM matrix elements, we fix $\lambda = 0.2196$, and take the central values of $| V_{cb} |= 0.0412 \pm 0.002$, $| \frac{V_{ub}}{V_{cb}} |= 0.087 \pm 0.018$ [18]. We fix the CP violating phase $\gamma$ to $53.6^\circ$ from global fitting of CKM parameters. With the above input parameters, the SM contributions are fixed. However, in SUSY the branching ratios depend on several parameters, such as $(\delta_{j3})_{LL}$, the squark mass $m_{\tilde{q}}$, and the ratio $x = m_{\tilde{g}}^2/m_{\tilde{q}}^2$. We treat $m_{\tilde{q}}$ and $x$ as free parameters and constrain $(\delta_{j3})_{LL}$ from the available experimental data. Our main aim will be to obtain limits on the complex plane of the flavor changing parameters $(\delta_{j3})_{LL}$ for a given $x$ and the squark mass. Otherwise mentioned, throughout our analysis we will use 100 GeV for squark mass. Constraints on $(\delta_{j3})_{LL}$ for other values of $m_{\tilde{q}}$ can be obtained by rescaling the constraint by $(m_{\tilde{q}}/100 \text{ GeV})^2$.

In the theoretical computations of the branching ratios, there are many sources of uncertainties, mainly arising from different form factors, CKM matrix elements, the annihilation contribution and other hadronic parameters of the QCD improved factorization methods. We have taken the default values of the above quantities following [2] to get the central values of the theoretically calculated branching ratios. However, the results may change if one varies any of the above parameters within their allowed range. To take into account this fact we conservatively allow an extra 50% variation in the theoretically calculated branching ratios from their default values. In the later section we will discuss more on these uncertainties. The input values chosen here are for an illustration. The main issue of our analysis is to show that $B \to PP$ can provide comparable or even better constraints in certain area of SUSY parameter space compared with other well known rare processes for B mesons, like $b \to s\gamma$, $B \to \rho\gamma$, and the mixing parameters $\Delta m_{B_s}$ and $\Delta m_{B_d}$.

## IV. $B \to PP(\Delta S = -1)$, $B \to S\gamma$ AND $B_S^0 - \bar{B}_S^0$ MIXING

In this section we study constraints on the parameter $(\delta_{23})_{LL}$ from $B \to K\pi$ and compare with the constraint from $b \to s\gamma$. We also comment on how $B_s^0 - \bar{B}_s^0$ mixing can provide information of FCNC parameters in SUSY. Since we are primarily interested in constraining the flavor changing parameter $(\delta_{23})_{LL}$, we will present our results on the complex plane of the $(\delta_{23})_{LL}$ for a given value of $m_{\tilde{q}}$ and $x$.

(a) $\bar{B}^0 \to K^+\pi^-$ (b) $B^- \to K^-\pi^0$



(c) $B^- \to \bar{K}^0\pi^-$ (d) $\bar{B}^0 \to \bar{K}^0\pi^0$

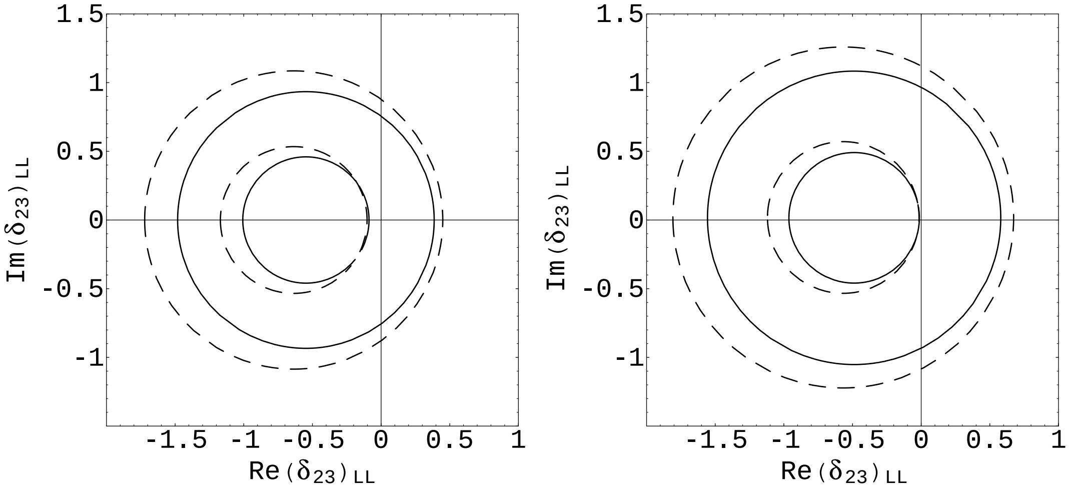


FIG. 1. The $2\sigma$ allowed region on $(\delta_{23})_{LL}$ complex plane from $B \to K\pi$ with $m_{\tilde{q}} = 100$ GeV. The solid and dashed bands are the allowed regions corresponding to $x = 1$ and 4 respectively.

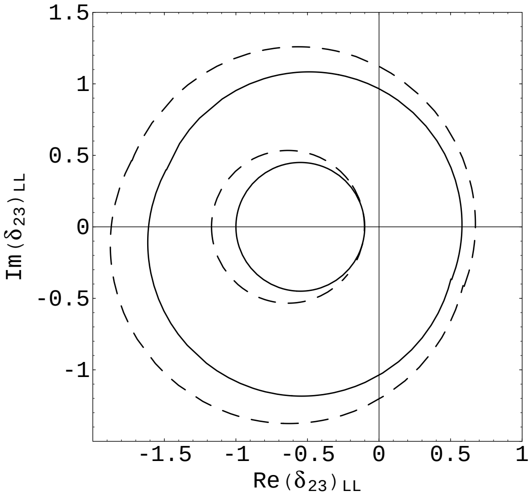

FIG. 2. Combined $2\sigma$ allowed region on $(\delta_{23})_{LL}$ complex plane obtained from four $B \to K\pi$ modes as shown in Figure 1. Other notations are same as Figure 1.

In Figure 1 we show $2\sigma$ allowed bands on the $(\delta_{23})_{LL}$ complex plane for two representative values of $x = 1$(solid line) and 4(dashed line) for the squark mass set at 100 GeV. From the above Figure with $m_{\tilde{q}}$=100 GeV, it is clear that the four different decay channels of $B$ into $K^+\pi^-, K^-\pi^0, \bar{K}^0\pi^-, \bar{K}^0\pi^0$ give almost similar limits and the allowed ranges are almost smaller than 1 on the $(\delta_{23})_{LL}$ complex plane. There is no significant change in the obtained bound even when $x$ varies in the range $0.5 \sim 10$. We finally combine the results obtained from these four branching ratios and display it in Figure 2. We see that the flavor changing parameter $(\delta_{23})_{LL}$ is constrained.

If the squark mass $m_{\tilde{q}}$ is different than the value 100 GeV used here, one can obtain the corresponding constraint on $(\delta_{23})_{LL}$ by multiplying a scaling factor $m_{\tilde{q}}^2/(100\ GeV)^2$ on $(\delta_{23})_{LL}$. We would like to point out, however, that when making such a rescaling one should be cautious about the applicability of the mass insertion method used to obtain the effective Hamiltomian. One should only apply the results to regions where $(\delta_{23})_{LL}$ is not larger than of order one. Since the constraint on $(\delta_{23})_{LL}$ is already of order one for $m_{\tilde{q}}$ about 100 GeV, for a larger $m_{\tilde{q}}$ $B \to PP$ give weak constraints on the flavor changing parameters.

We now compare the above constraints with that from $b \to s\gamma$. We take the current experimental world average result $Br(B \to X_s\gamma) = (3.41 \pm 0.36) \times 10^{-4}$ [19] from CLEO, ALEPH, Belle and Babar. This process is another rare process which is sensitive to new physics with $\Delta S = -1$ and has been used to constrain new physics beyond the SM.

The branching ratio of $b \to s\gamma$ is given by [20,21]

$$Br(B \to X_s\gamma) = Br(B \to Xe\bar{\nu}_e)\frac{|V_{ts}^* V_{tb}|^2}{|V_{cb}|^2}\frac{6\alpha_{em}}{\pi g(m_c/m_b)\eta}|c_{12}(m_b)|^2 \,, \tag{18}$$

where $c_{12}(m_b) = c_{12}^{SM}(m_b) + c_{12}^{susy}(m_b)$, $g(z) = 1 - 8z^2 + 8z^6 - z^8 - 24z^4 ln(z)$, and $\eta = 1 - 2f(r,0,0)\alpha_s(m_b)/3\pi$ with $f(r,0,0) = 2.41$ [21]. The running of the supersymmetric WC's $c_{11,12}^{susy}$ are given by [22]

$$c_{11}^{susy}(\mu) = \eta c_{11}^{susy}(M_{susy}), \;\; c_{12}^{susy}(\mu) = \eta^2 c_{12}^{susy}(M_{susy}) + \frac{8}{3}(\eta - \eta^2)c_{11}^{susy}(M_{susy}), \tag{19}$$

where $\eta = (\alpha_s(M_{susy})/\alpha_s(m_t))^{2/21}(\alpha_s(m_t)/\alpha_s(m_b))^{2/23}$, with

$$\begin{aligned} c_{11}^{susy}(M_{susy}) &= \frac{-\alpha_s \pi (\delta_{j3})_{LL}}{m_{\tilde{q}}^2 \sqrt{2} G_F V_{tb} V_{tq}^*}\Big(-\frac{1}{3}M_3(x) - 3M_4(x)\Big) \\ c_{12}^{susy}(M_{susy}) &= \frac{-\alpha_s \pi (\delta_{j3})_{LL}}{m_{\tilde{q}}^2 \sqrt{2} G_F V_{tb} V_{tq}^*}\Big(-\frac{1}{3}\frac{8}{3}M_3(x)\Big) \end{aligned} \tag{20}$$

The functions $M_{3,4}(x)$ are defined in Ref. [6]. Here we use the leading order result for $b \to s\gamma$. The use of the NLO result [23] will change the LO results by about 10%, which will not affect our main conclusion.

The $2\sigma$ constraints on $(\delta_{23})_{LL}$ complex plane from $b \to s\gamma$ for two different values of $x = 1$ and 4 are shown in Figure 3. From this figure we see that as $x$ increases the limit on $(\delta_{23})_{LL}$ from $b \to s\gamma$ become weaker.

It was thought that $b \to s\gamma$ gives the strongest limit on the parameter $(\delta_{23})_{LL}$. However, in our analysis we find that in certain region of the parameter space the bounds obtained from $B \to K\pi$ are stronger than the limit obtained from $b \to s\gamma$. From Figure 4 we see that for $x = 8$ constraints from $B \to K\pi$ provide slightly better constraints than that from $b \to s\gamma$. We find that for $x$ less than 8, the constraints obtained from $B \to PP$ are not as strong as that from $b \to s\gamma$. But for $x$ larger than 8, the constraints from $B \to PP$ is more stringent.

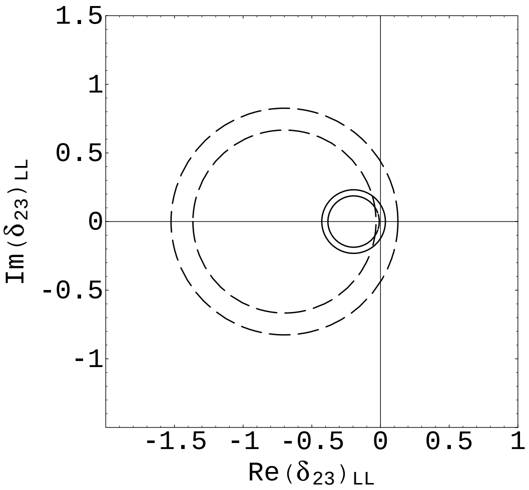

FIG. 3. The $2\sigma$ allowed bands obtained from $b \to s\gamma$ on the complex $(\delta_{23})_{LL}$ plane with $m_{\tilde{q}} = 100$ GeV. Other notations are same as Figure 1.

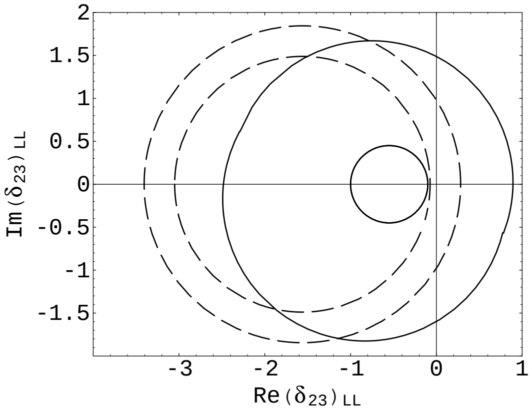

FIG. 4. Combined $2\sigma$ allowed region on $(\delta_{23})_{LL}$ complex plane obtained from $B \to K\pi$ (solid band) and $b \to s\gamma$ (dashed band) for $x = 8$ with $m_{\tilde{q}} = 100$ GeV.

One can easily understand the above results from the $x$ dependence of SUSY contributions to $B \to K\pi$ and $b \to s\gamma$. From Eq. 7, we find that the SUSY contributions mainly appear in parameters $a_4$ and $a_6$ through $C^{total}_{3,4,5,6}$.

$$a^{susy} = a_4^{susy} + a_6^{susy} = C_4^{LL} + \frac{C_3^{LL}}{N} + R_{\pi,K}(C_6^{LL} + \frac{C_5^{LL}}{N}). \tag{21}$$

We have checked numerically that the other contributions in Eq. 7 from SUSY interactions are small.

The parameter $a^{susy}$ linearly depends on $(\delta_{j3})_{LL}/m_{\tilde{q}}^2$ and depends on $x$ in a complicated but known form which we indicate as $a^{susy} = a^{susy}(x)$. One can easily study how experimental data may constrain the parameter $(\delta_{j3})_{LL}/m_{\tilde{q}}^2$ as a function of $x$ by studying the behavior of

$$R(PP) = \frac{a^{susy}(x)}{a^{susy}(1)}. \tag{22}$$

The above function shows the behavior of the SUSY contribution with $x$ normalized with the value at $x = 1$. In Figure 5, we show the behavior of $R(PP)$ as a function of $x$ by the dark solid line. From the figure we see that $R(PP)$ has a zero value at $x \simeq 0.37$. This implies that for $x \simeq 0.37$, no constraint on $(\delta_{23})_{LL}$ from $B \to PP$. In the neighborhood of this region $b \to s\gamma$ certainly give a better bound. For $x$ in the range $1 \sim 10$, $R(PP)$ varies very slowly with $x$. This almost flat behavior of $R(PP)$ makes the bound on $(\delta_{23})_{LL}$ to remain nearly unchanged within this range of $x$.

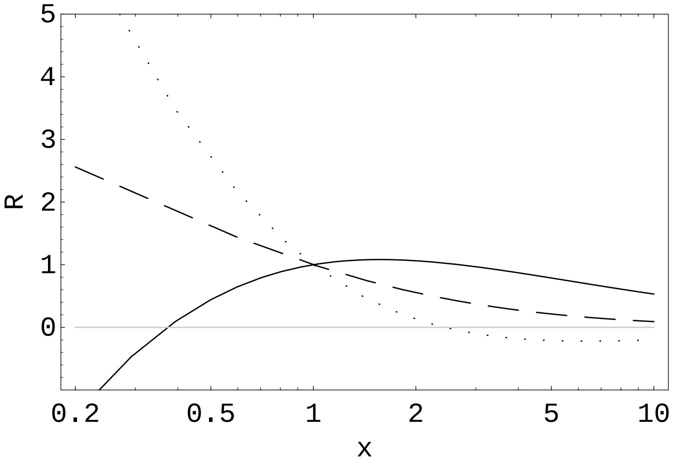

FIG. 5. $R(PP)$, $R(q\gamma)$ and $R(B^0_{d,s} - \bar{B}^0_{d,s})$ as functions of $x$. The solid, dashed and dotted lines correspond to $R(PP)$, $R(q\gamma)$, and $R(B^0_{d,s} - \bar{B}^0_{d,s})$, respectively.

While for $b \to s\gamma$, the SUSY contribution has a different $x$ dependence. In Figure 5 we show the variation of

$$R(q\gamma) = \frac{c_{12}^{susy}(x)}{c_{12}^{susy}(1)}, \tag{23}$$

as a function of $x$ by the dashed line. We see that $R(q\gamma)$ decreases when $x$ increases. This means, for a given $m_{\tilde{q}}$, the constraint on $(\delta_{23})_{LL}$ becomes weaker as $x$ increases. At certain value of $x$, $B \to K\pi$ give better bounds than $b \to s\gamma$. Numerically we find that when $x$ is larger than 8, $B \to K\pi$ give better constraints on $(\delta_{23})_{LL}$ than $b \to s\gamma$.

We now comment on the implications of $q - \tilde{q} - \tilde{g}$ interactions on $B_s^0 - \bar{B}_s^0$ mixing. The effective Hamiltonian for this process is given by [6]

$$H_{eff} = -C_m O_m \ , \tag{24}$$

$$C_m = \frac{\alpha_s^2}{216 m_{\tilde{q}}^2}[24x f_6(x) + 66\tilde{f}_6(x)](\delta_{j3})^2_{LL} \ , \tag{25}$$

$$O_m = \bar{s}_L^\alpha \gamma_\mu b_L^\alpha \bar{s}_L^\beta \gamma_\mu b_L^\beta \tag{26}$$

The functions $f_6(x)$ and $\tilde{f}_6(x)$ are given by:

$$f_6(x) = \frac{6(1+3x)\ln(x) + x^3 - 9x^2 - 9x + 17}{6(1-x)^5} \ , \tag{27}$$

$$\tilde{f}_6(x) = \frac{6x(1+x)\ln(x) - x^3 - 9x^2 + 9x + 1}{3(1-x)^3} \ . \tag{28}$$

After RG evolution we get the WC at $m_b$ scale [24]:

$$C_m(m_b) = \eta_1 C_m(M_{susy}) \ , \tag{29}$$

$$\eta_1 = \Big(\frac{\alpha_s(m_t)}{\alpha_s(m_b)}\Big)^{6/23}\Big(\frac{\alpha_s(M_{susy})}{\alpha_s(m_t)}\Big)^{6/21} \ , \tag{30}$$

the total $\Delta M_{B_s}$ is given by $\Delta M_{B_s}$=$2|M_{12}^{SM}$+$M_{12}^{susy}|$ with $M_{12}^{susy} = \eta_1 (C_m/3) M_{B_s} B_{B_s} f_{B_s}^2$. The SM contribution $M_{12}^{SM}$ is given by [25], and $M_{12}^{susy}$ contains phase from parameter $(\delta_{j3})^2_{LL}$. At present we have only stringent lower bound on $\Delta M_{B_s}$ which is 14.4 $ps^{-1}$ at the 95% C.L. [26]. Using previously obtained constraints one can obtain the allowed range for $\Delta M_{B_s}$ with SUSY contributions. In our numerical calculation we use [18] $\xi \equiv \sqrt{B_{B_s}}/f_{B_s}\sqrt{B_{B_d}} f_{B_d} = 1.16 \pm 0.05$ and $\sqrt{B_{B_d}} f_{B_d} = 230 \pm 40 MeV$.

We find that $B \to K\pi$ and $b \to s\gamma$ data do not constrain $\Delta M_{B_s}$ significantly in a large part of the parameter space allowing $\Delta M_{B_s}$ to be much larger than the present lower bound. If future experiments can measure $\Delta M_{B_s}$ of the order or less than $\sim 48\ ps^{-1}$, which is the limit LHCb can reach, then, one would obtain a much stronger limit on $(\delta_{23})_{LL}$ for $x = 1$ and 4 as shown in Figure 6. However we still find that there are regions where

$B \to K\pi$ and $b \to s\gamma$ give better constraints. To see in which area of parameter space, the SUSY contributions to $\Delta M_{B_s}$ become negligible , we study the behavior of relative SUSY contribution, $R(B_s^0 - \bar{B}_s^0) = C_m(x)/C_m(1)$ as a function of $x$. In Figure 5 we show the variation of $R(B_s^0 - \bar{B}_s^0)$ as a function of $x$ by the dotted lines. we see that at $x = 2.43$ SUSY contribution to $\Delta M_{B_s}$ becomes zero and no constraint on $(\delta_{23})_{LL}$ can be obtained. In regions around $x = 2.43$, $B \to K\pi$ and $b \to s\gamma$ can give better constraints even if we assume that the future experiment will measure a $\Delta M_{B_s}$ less than 48 $ps^{-1}$.

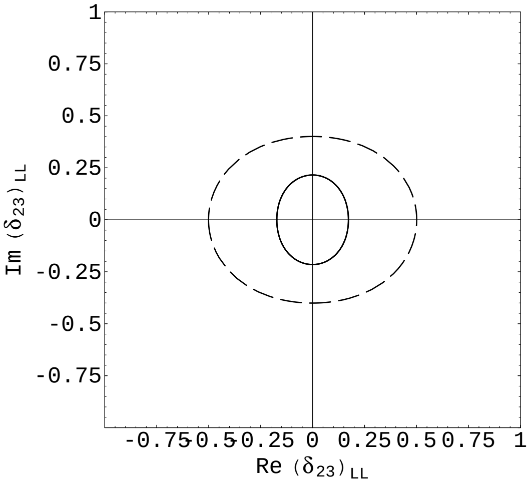

FIG. 6. The allowed areas (areas inside each curve are excluded if $\Delta M_{B_s}$ is larger than 48 $ps^{-1}$) with solid and dashed boundaries corresponding to $x = 1$ and 4 respectively on the complex plane of $(\delta_{23})_{LL}$.

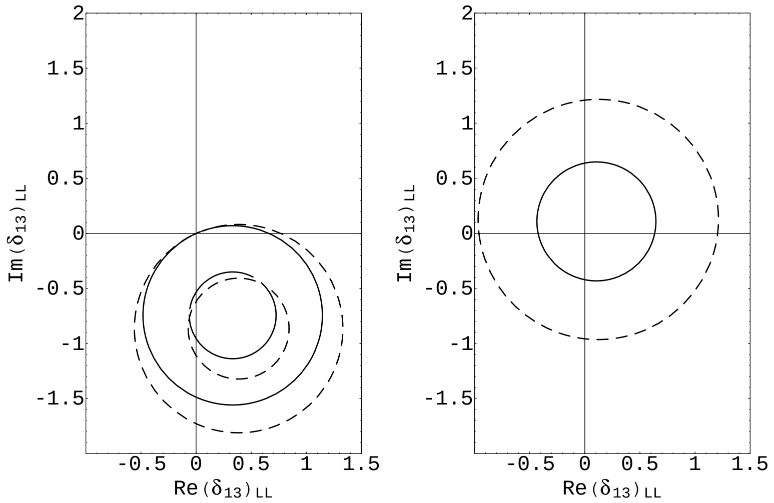
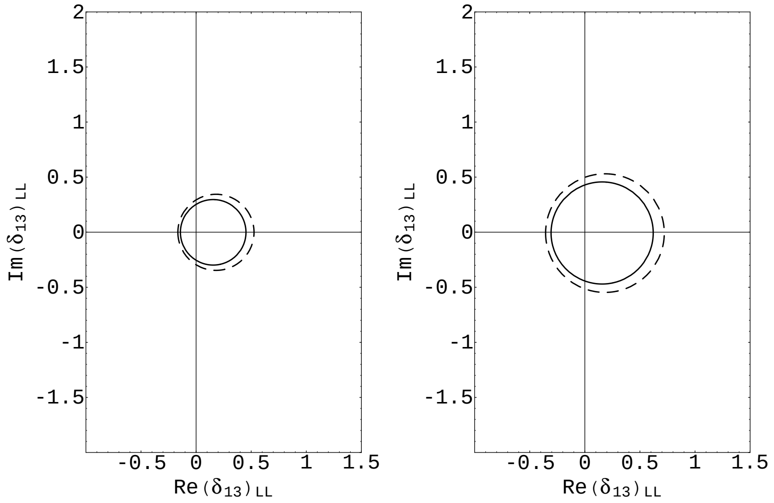
## V. $B \to PP(\Delta S = 0)$, $B \to \rho\gamma$ AND $B_D - \bar{B}_D$ MIXING

In this section we discuss constraints on SUSY interactions from following processes: $B \to \pi\pi, KK$, $B \to \rho\gamma$ and $\Delta M_{B_d}$. Constraints obtained from $B \to \pi\pi$ and $B \to KK$ are shown in Figure 7. We find that the constraints on $(\delta_{13})_{LL}$ are better than $(\delta_{23})_{LL}$ obtained from $B \to K\pi$ decays. The strongest one is obtained from $B^- \to K^- K^0$.

Although $B \to \rho\gamma$ has not been measured, the experimental upper bound from BaBar $Br(B^0 \to \rho^0\gamma) \leq 1.4 \times 10^{-6}$ at the 90%C.L. [27] has been used to obtain a constraint on



(a) $\bar{B}^0 \to \pi^+\pi^-$ (b) $\bar{B}^0 \to \pi^0\pi^0$



(c) $B^- \to K^- K^0$ (d) $\bar{B}^0 \to K^0 \bar{K}^0$

FIG. 7. The constraint on $(\delta_{13})_{LL}$ from $B \to \pi\pi$, $B \to K\bar{K}$. For $B \to \pi^+\pi^-$ are $2\sigma$ allowed region while for $B \to \pi^0\pi^0$, $B \to K^-K^0$ and $B \to K^0\bar{K}^0$ is the limits with 90%C.L. The solid and dashed bands (a) and circles ((b)-(d)) are the allowed regions corresponding to $x = 1$ and 4 respectively.

$(\delta_{13})_{LL}$. The decay width $\Gamma(B \to \rho\gamma)$ is given by:

$$\Gamma(B \to \rho\gamma) = \frac{\alpha_{em}}{32\pi^4} G_F^2 |V_{tb}|^2 |V_{td}^*| |F^{B\to\rho}(0)|^2 |c_{12}(m_b)|^2 (m_b^2 + m_d^2) \frac{(m_B^2 - m_\rho^2)^3}{m_B^3} \tag{31}$$

We use the form factor calculated by T. Huang *et al.* in Ref. [28], $F^{B\to\rho^0} = 0.237 \pm 0.035$. The constraints on $(\delta_{13})_{LL}$ for $x = 1$ and 4 are shown in Figure 8. Comparing the constraints obtained from $B \to \pi\pi, KK$ with $B \to \rho\gamma$ we find that similar to the discussions in the previous section, when $x$ becomes larger the constraint from $B^- \to K^- K^0$ become relatively better than $B \to \rho\gamma$, numerically for the strongest case $B^- \to K^- K^0$, this occurs at $x$ about 6.

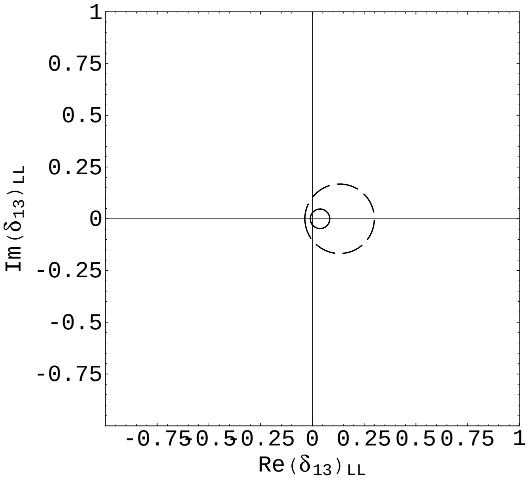


FIG. 8. The constraint of $(\delta_{13})_{LL}$ from $B \to \rho\gamma$. The allowed area marked by solid and dashed line correspond to $x = 1$ and 4 respectively.

We now turn to constraint from $\Delta M_{B_d}$. This quantity has been experimentally well measured with the world average value [18] $0.489 \pm 0.008\ ps^{-1}$. However, the theoretical calculation has uncertainty from $\sqrt{B_d} f_{B_d}$, which is $230 \pm 40$ MeV. The results are shown in Figure 9. It can be seen that $\Delta M_{B_d}$ provides a much stronger constraint on $(\delta_{13})_{LL}$ compared with the constraint on $(\delta_{23})_{LL}$ from $\Delta M_{B_s}$. In a large part of the parameter space the branching ratios $B \to \pi\pi$, $B \to K\bar{K}$ provide weaker constraints on $(\delta_{13})_{LL}$ unless $x$ is close to 2.43 where SUSY contribute to $\Delta M_{B_d}$ is zero as can be seen from Figure 5. In the region around $x = 2.43$ $B \to K^- K^0$ and $B \to \rho\gamma$ give better bounds.

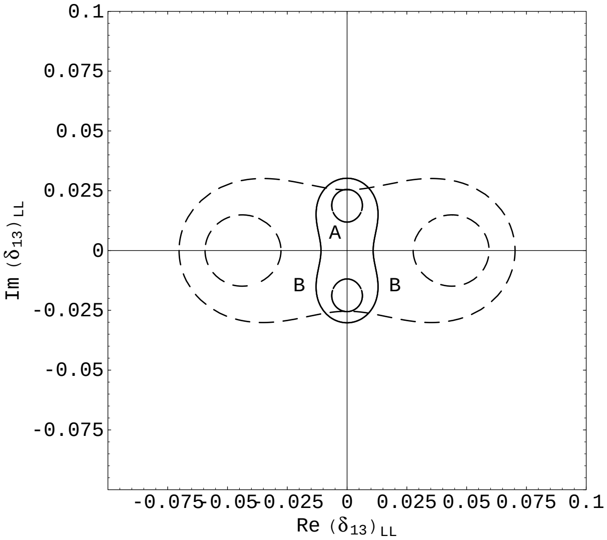

FIG. 9. The areas marked by "A" and "B" on the complex $(\delta_{23})_{LL}$ plane represent $2\sigma$ allowed regions for $x = 1$ and 4 respectively obtained from $B_d - \bar{B}_d$ mixing.

## VI. CONSTRAINTS ON $(\delta_{IJ})_{RR}$

In the previous discussions, we have concentrated on constraints on $(\delta_{ij})_{LL}$. We now discuss constraints on $(\delta_{ij})_{RR}$. Due to the different chirality of the new operators the total WC's, in the theoretical expressions for $B \to PP$, are replaced by $C^{total}_{3,4,5,6} = C^{SM}_{3,4,5,6} - C^{RR}_{3,4,5,6}$, where $C^{RR}_{3,4,5,6}$ have the same form as for $C^{LL}_{3,4,5,6}$ in Eq. 3 with $(\delta_{ij})_{LL}$ replaced by $(\delta_{ij})_{RR}$.

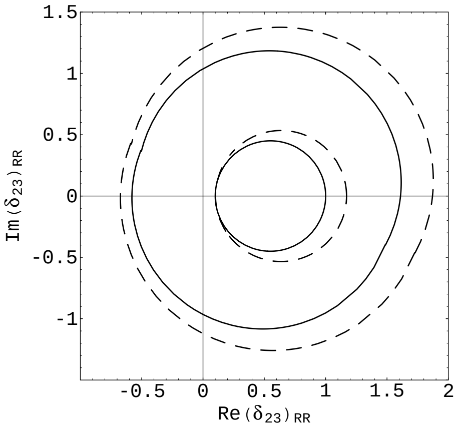

FIG. 10. Combined ($\bar{B}^0 \to K^+\pi^-,\ \bar{K}^0\pi^0$) and ($B^- \to K^-\pi^0,\ \bar{K}^0\pi^-$) constraints on $(\delta_{23})_{RR}$ with $m_{\tilde{q}} = 100$ GeV.

In Figure 10, we present the combined ($\bar{B}^0 \to K^+\pi^-,\ \bar{K}^0\pi^0$) and ($B^- \to K^-\pi^0,\ \bar{K}^0\pi^-$) constraints on $(\delta_{23})_{RR}$. The allowed ranges are the same but as a mirror reflection in complex plane of $(\delta_{ij})_{RR}$ compared with that of $(\delta_{ij})_{LL}$.

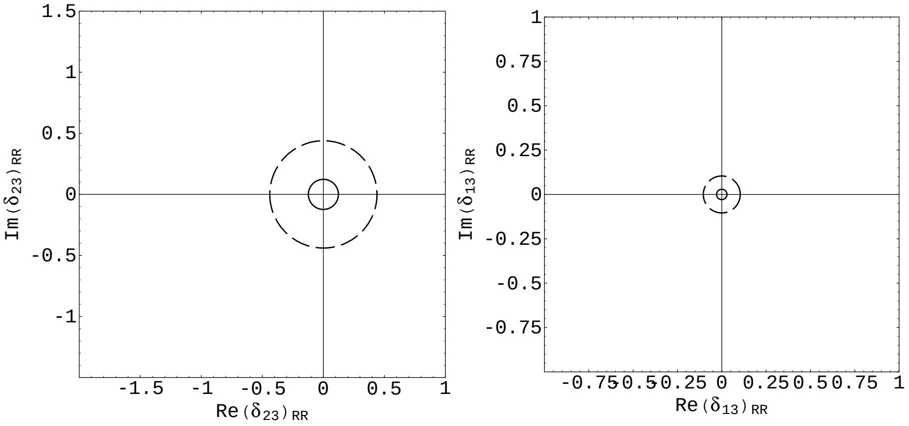

FIG. 11. $b \to s\gamma$ and $B \to \rho\gamma$ on $(\delta_{23})_{RR}$ with $m_{\tilde{q}} = 100$ GeV.

In $b \to s\gamma$ and $B \to \rho\gamma$ cases, because of different chirality in operators, the Wilson coefficient $c_{12}^{susy}$ is separated from the SM contribution $c_{12}^{SM}$. One needs to replace $|c_{12}(m_b)|^2$ in Eq. 18 and Eq. 31 by $|c_{12}(m_b)|^2 = |c_{12}^{SM}|^2 + |c_{12}^{susy}|^2$. The allowed ranges are shown in Figure 11. We see that they are different than those shown in Figures 3 and 8. It is clear that the allowed ranges of $(\delta_{ij})_{RR}$ are constrained to be smaller than $(\delta_{ij})_{LL}$.

$B_{d,s} - \bar{B}_{d,s}$ mixing also constrain $(\delta_{ij})_{RR}$. In this case one just needs to replace $(\delta_{ij})_{LL}$ in Eq. 25 by $(\delta_{ij})_{RR}$ and $Q_m = \bar{s}_L^\alpha \gamma_\mu b_L^\alpha \bar{s}_L^\beta \gamma_\mu b_L^\beta$ by $\tilde{Q}_m = \bar{s}_R^\alpha \gamma_\mu b_R^\alpha \bar{s}_R^\beta \gamma_\mu b_R^\beta$. Since $\langle B^0 | Q_m | \bar{B}^0 \rangle = \langle B^0 | \tilde{Q}_m | \bar{B}^0 \rangle$, the constraints on $(\delta_{ij})_{RR}$ from $\Delta m_{B_{d,s}}$ are the same as in Figures 6 and 9.

## VII. CONCLUSIONS

In this paper we studied the constraints on the SUSY flavor changing parameters $(\delta_{13})_{LL,RR}$ and $(\delta_{23})_{LL,RR}$ from rare hadronic $B \to PP$ decays. We improved the calculations by two folds. Firstly, all the relevant Wilson coefficients are computed at $M_{susy}$ and then evolved down to lower scale $\mu = m_b$ using Renormalization Group Equation. Secondly, we calculated the two body hadronic $B$ decays using QCD improved factorization method.

We found that the values of the Wilson coefficients do change significantly under this evolution which in turn affect the theoretical computation of $B$ decays. The constraints obtained are compared with radiative $b \to s\gamma$ and $B \to \rho\gamma$ decays, and $\Delta M_{B_{d,s}}$.

We found that each of the different processes discussed can provide interesting constraints on the SUSY flavor changing parameters within certain parameter space. For $(\delta_{23})_{LL,RR}$ we found that as long as $x \leq 7$, $b \to s\gamma$ provides the most stringent limit, however, for $x \geq 8$, $B \to K\pi$ give better constraints. For $(\delta_{13})_{LL,RR}$ we observed $\Delta M_{B_d}$ provides a better bound, but for $x$ around 2.43, the bound becomes weaker. In this region, $B \to K^- K^0$ and $B \to \rho\gamma$ can give stronger constraint.

Before we conclude, we would like to comment on the possible theoretical uncertainties arising from different form factors, CKM elements, the hard spectator interactions and also from annihilation contributions in QCD improved factorization scheme. As we have already mentioned earlier that these hard spectator interactions and annihilation contributions in QCD improved factorization method suffer from endpoint singularities and these singularities have been treated as a phenomenological parameters inducing model dependence and additional source of numerical uncertainties. However, the exact estimations of these uncertainties are not yet known. The uncertainties in the different form factors can change the theoretical results by about 40%. We think that the overall uncertainty could be around 50%. So, in our theoretical calculations we have taken into account this 50% uncertainty to obtain the limits. In our calculations we also fixed the SM phase $\gamma$ to be $53.6^\circ$. When SUSY contributions are included, the $\gamma$ phase will differ from its SM value. Allowing $\gamma$ to vary will also change the details of the numerical results.

However our main objective here was to explore all possible $B \to PP$ decays within the context of SUSY and show how in different regions of parameter space the different decay modes can constrain the FCNC parameters. The generic feature of our analysis will not change significantly by the above mentioned different uncertainties. A coherent study of different processes involving $B$-mesons carried out here can serve to provide detailed information about the SUSY FCNC parameters. We hope in future with the improved theoretical calculations and data will provide a better understanding of SUSY flavor changing interactions.
